

INTRODUCTION TO PYTHON PROGRAMMING

- Lecture three -

PRESENTED BY YOUSSEF KHALIL

Session Agenda

PYTHON & DATA STRUCTURE

Python Collections (Arrays)

There are four collection data types in the Python programming language:

- **List** is a collection which is ordered and changeable. Allows duplicate members.
- **Tuple** is a collection which is ordered and unchangeable. Allows duplicate members.
- **Set** is a collection which is unordered and unindexed. No duplicate members.
- **Dictionary** is a collection which is ordered* and changeable. No duplicate members.

List

Lists are used to store multiple items in a single variable.

Lists are one of 4 built-in data types in Python used to store collections of data, the other 3 are [Tuple](#), [Set](#), and [Dictionary](#), all with different qualities and usage.

Lists are created using square brackets:

Example

Create a List:

```
thislist = ["apple", "banana", "cherry"]  
print(thislist)
```

[Try it Yourself »](#)

List Items

List items are ordered, changeable, and allow duplicate values.

List items are indexed, the first item has index `[0]`, the second item has index `[1]` etc.

Ordered

When we say that lists are ordered, it means that the items have a defined order, and that order will not change.

If you add new items to a list, the new items will be placed at the end of the list.

Changeable

The list is changeable, meaning that we can change, add, and remove items in a list after it has been created.

Allow Duplicates

Since lists are indexed, lists can have items with the same value:

Example

Lists allow duplicate values:

```
thislist = ["apple", "banana", "cherry", "apple", "cherry"]  
print(thislist)
```

[Try it Yourself »](#)

List Length

To determine how many items a list has, use the `len()` function:

Example

Print the number of items in the list:

```
thislist = ["apple", "banana", "cherry"]  
print(len(thislist))
```

[Try it Yourself »](#)

List Items - Data Types

List items can be of any data type:

Example

String, int and boolean data types:

```
list1 = ["apple", "banana", "cherry"]  
list2 = [1, 5, 7, 9, 3]  
list3 = [True, False, False]
```

[Try it Yourself »](#)

A list can contain different data types:

Example

A list with strings, integers and boolean values:

```
list1 = ["abc", 34, True, 40, "male"]
```

[Try it Yourself »](#)

type()

From Python's perspective, lists are defined as objects with the data type 'list':

```
<class 'list'>
```

Example

What is the data type of a list?

```
mylist = ["apple", "banana", "cherry"]  
print(type(mylist))
```

[Try it Yourself »](#)

The list() Constructor

It is also possible to use the `list()` constructor when creating a new list.

Example

Using the `list()` constructor to make a List:

```
thislist = list(("apple", "banana", "cherry")) # note the double round-brackets  
print(thislist)
```

[Try it Yourself »](#)

List Methods

Python has a set of built-in methods that you can use on lists.

Method	Description
<code>append()</code>	Adds an element at the end of the list
<code>clear()</code>	Removes all the elements from the list
<code>copy()</code>	Returns a copy of the list
<code>count()</code>	Returns the number of elements with the specified value
<code>extend()</code>	Add the elements of a list (or any iterable), to the end of the current list
<code>index()</code>	Returns the index of the first element with the specified value
<code>insert()</code>	Adds an element at the specified position
<code>pop()</code>	Removes the element at the specified position
<code>remove()</code>	Removes the item with the specified value
<code>reverse()</code>	Reverses the order of the list
<code>sort()</code>	Sorts the list

LIST EXERCISE

1. Write a Python program to sum all the items in a list. [Go to the editor](#)

[Click me to see the sample solution](#)

main.py			Run	Shell
<pre>1 my_list = [5,6,8,9,2,4,35,9,2] 2 sum = 0 3 4 for i in range (0, len(my_list)): 5 sum += my_list[i] 6 print(sum) 7</pre>				<pre>80 > </pre>

LIST EXERCISE

2. Write a Python program to multiply all the items in a list. [Go to the editor](#)

[Click me to see the sample solution](#)

main.py	<div><div>⌕</div><div>🌙</div><div>Run</div></div>	Shell
<pre>1 my_list = [5,6,8,9,2,4,35,9,2] 2 sum = 1 3 4 for i in range (0, len(my_list)): 5 sum *= my_list[i] 6 print(sum) 7</pre>	<pre>10886400 > </pre>	

LIST EXERCISE

3. Write a Python program to get the largest number from a list. [Go to the editor](#)

[Click me to see the sample solution](#)

main.py	  	Shell
<pre>1 my_list = [5,6,8,9,2,4,35,9,2] 2 3 largest = my_list[0] 4 5 for i in range(0,len(my_list)) : 6 if my_list[i] > largest: 7 largest = my_list[i] 8 9 print (largest) 10</pre>		<pre>35 > </pre>

LIST EXERCISE

4. Write a Python program to get the smallest number from a list. [Go to the editor](#)

[Click me to see the sample solution](#)

main.py

Run

Shell

```
1 my_list = [5,6,8,9,2,4,35,9,2]
2
3 largest = my_list[0]
4
5 for i in range(0,len(my_list)) :
6     if my_list[i] < largest:
7         largest = my_list[i]
8
9 print (largest)
10
```

```
2
> |
```

Access Items

List items are indexed and you can access them by referring to the index number:

Example

Print the second item of the list:

```
thislist = ["apple", "banana", "cherry"]  
print(thislist[1])
```

[Try it Yourself »](#)

Negative Indexing

Negative indexing means start from the end

`-1` refers to the last item, `-2` refers to the second last item etc.

Example

Print the last item of the list:

```
thislist = ["apple", "banana", "cherry"]  
print(thislist[-1])
```

[Try it Yourself »](#)

Range of Indexes

You can specify a range of indexes by specifying where to start and where to end the range.

When specifying a range, the return value will be a new list with the specified items.

Example

Return the third, fourth, and fifth item:

```
thislist = ["apple", "banana", "cherry", "orange", "kiwi", "melon", "mango"]  
print(thislist[2:5])
```

[Try it Yourself »](#)

By leaving out the start value, the range will start at the first item:

Example

This example returns the items from the beginning to, but NOT including, "kiwi":

```
thislist = ["apple", "banana", "cherry", "orange", "kiwi", "melon", "mango"]  
print(thislist[:4])
```

[Try it Yourself »](#)

By leaving out the end value, the range will go on to the end of the list:

Example

This example returns the items from "cherry" to the end:

```
thislist = ["apple", "banana", "cherry", "orange", "kiwi", "melon", "mango"]  
print(thislist[2:])
```

[Try it Yourself »](#)

Range of Negative Indexes

Specify negative indexes if you want to start the search from the end of the list:

Example

This example returns the items from "orange" (-4) to, but NOT including "mango" (-1):

```
thislist = ["apple", "banana", "cherry", "orange", "kiwi", "melon", "mango"]  
print(thislist[-4:-1])
```

[Try it Yourself »](#)

Check if Item Exists

To determine if a specified item is present in a list use the `in` keyword:

Example

Check if "apple" is present in the list:

```
thislist = ["apple", "banana", "cherry"]  
if "apple" in thislist:  
    print("Yes, 'apple' is in the fruits list")
```

[Try it Yourself »](#)

Append Items

To add an item to the end of the list, use the `append()` method:

Example

Using the `append()` method to append an item:

```
thislist = ["apple", "banana", "cherry"]  
thislist.append("orange")  
print(thislist)
```

[Try it Yourself »](#)

Insert Items

To insert a list item at a specified index, use the `insert()` method.

The `insert()` method inserts an item at the specified index:

Example

Insert an item as the second position:

```
thislist = ["apple", "banana", "cherry"]  
thislist.insert(1, "orange")  
print(thislist)
```

[Try it Yourself »](#)

Extend List

To append elements from *another list* to the current list, use the `extend()` method.

Example

Add the elements of `tropical` to `thislist`:

```
thislist = ["apple", "banana", "cherry"]  
tropical = ["mango", "pineapple", "papaya"]  
thislist.extend(tropical)  
print(thislist)
```

[Try it Yourself »](#)

Add Any Iterable

The `extend()` method does not have to append *lists*, you can add any iterable object (tuples, sets, dictionaries etc.).

Example

Add elements of a tuple to a list:

```
thislist = ["apple", "banana", "cherry"]  
thistuple = ("kiwi", "orange")  
thislist.extend(thistuple)  
print(thislist)
```

[Try it Yourself »](#)

Remove Specified Item

The `remove()` method removes the specified item.

Example

Remove "banana":

```
thislist = ["apple", "banana", "cherry"]  
thislist.remove("banana")  
print(thislist)
```

[Try it Yourself »](#)

Remove Specified Index

The `pop()` method removes the specified index.

Example

Remove the second item:

```
thislist = ["apple", "banana", "cherry"]  
thislist.pop(1)  
print(thislist)
```

[Try it Yourself »](#)

If you do not specify the index, the `pop()` method removes the last item.

Example

Remove the last item:

```
thislist = ["apple", "banana", "cherry"]  
thislist.pop()  
print(thislist)
```

[Try it Yourself »](#)

The `del` keyword also removes the specified index:

Example

Remove the first item:

```
thislist = ["apple", "banana", "cherry"]  
del thislist[0]  
print(thislist)
```

[Try it Yourself »](#)

The `del` keyword can also delete the list completely.

Example

Delete the entire list:

```
thislist = ["apple", "banana", "cherry"]  
del thislist
```

[Try it Yourself »](#)

Clear the List

The `clear()` method empties the list.

The list still remains, but it has no content.

Example

Clear the list content:

```
thislist = ["apple", "banana", "cherry"]  
thislist.clear()  
print(thislist)
```

[Try it Yourself »](#)

Loop Through a List

You can loop through the list items by using a `for` loop:

Example

Print all items in the list, one by one:

```
thislist = ["apple", "banana", "cherry"]  
for x in thislist:  
    print(x)
```

[Try it Yourself »](#)

Loop Through the Index Numbers

You can also loop through the list items by referring to their index number.

Use the `range()` and `len()` functions to create a suitable iterable.

Example

Print all items by referring to their index number:

```
thislist = ["apple", "banana", "cherry"]  
for i in range(len(thislist)):  
    print(thislist[i])
```

[Try it Yourself »](#)

Using a While Loop

You can loop through the list items by using a `while` loop.

Use the `len()` function to determine the length of the list, then start at 0 and loop your way through the list items by referring to their indexes.

Remember to increase the index by 1 after each iteration.

Example

Print all items, using a `while` loop to go through all the index numbers

```
thislist = ["apple", "banana", "cherry"]  
i = 0  
while i < len(thislist):  
    print(thislist[i])  
    i = i + 1
```

[Try it Yourself »](#)

Looping Using List Comprehension

List Comprehension offers the shortest syntax for looping through lists:

Example

A short hand `for` loop that will print all items in a list:

```
thislist = ["apple", "banana", "cherry"]  
[print(x) for x in thislist]
```

[Try it Yourself »](#)

List Comprehension

List comprehension offers a shorter syntax when you want to create a new list based on the values of an existing list.

Example:

Based on a list of fruits, you want a new list, containing only the fruits with the letter "a" in the name.

Without list comprehension you will have to write a `for` statement with a conditional test inside:

Example

```
fruits = ["apple", "banana", "cherry", "kiwi", "mango"]
newlist = []

for x in fruits:
    if "a" in x:
        newlist.append(x)

print(newlist)
```

Example

With no `if` statement:

```
newlist = [x for x in fruits]
```

[Try it Yourself »](#)

With list comprehension you can do all that with only one line of code:

Example

```
fruits = ["apple", "banana", "cherry", "kiwi", "mango"]  
  
newlist = [x for x in fruits if "a" in x]  
  
print(newlist)
```

[Try it Yourself »](#)

The Syntax

```
newlist = [expression for item in iterable if condition == True]
```

The return value is a new list, leaving the old list unchanged.

Condition

The *condition* is like a filter that only accepts the items that valuate to `True`.

Example

Only accept items that are not "apple":

```
newlist = [x for x in fruits if x != "apple"]
```

[Try it Yourself »](#)

Iterable

The *iterable* can be any iterable object, like a list, tuple, set etc.

Example

You can use the `range()` function to create an iterable:

```
newlist = [x for x in range(10)]
```

[Try it Yourself »](#)

Expression

The *expression* is the current item in the iteration, but it is also the outcome, which you can manipulate before it ends up like a list item in the new list:

Example

Set the values in the new list to upper case:

```
newlist = [x.upper() for x in fruits]
```

[Try it Yourself »](#)

Sort List Alphanumerically

List objects have a `sort()` method that will sort the list alphanumerically, ascending, by default:

Example

Sort the list alphabetically:

```
thislist = ["orange", "mango", "kiwi", "pineapple", "banana"]  
thislist.sort()  
print(thislist)
```

[Try it Yourself »](#)

Example

Sort the list numerically:

```
thislist = [100, 50, 65, 82, 23]
thislist.sort()
print(thislist)
```

[Try it Yourself »](#)

Sort Descending

To sort descending, use the keyword argument `reverse = True`:

Example

Sort the list descending:

```
thislist = ["orange", "mango", "kiwi", "pineapple", "banana"]  
thislist.sort(reverse = True)  
print(thislist)
```

[Try it Yourself »](#)

Customize Sort Function

You can also customize your own function by using the keyword argument `key = function`.

The function will return a number that will be used to sort the list (the lowest number first):

Example

Sort the list based on how close the number is to 50:

```
def myfunc(n):  
    return abs(n - 50)  
  
thislist = [100, 50, 65, 82, 23]  
thislist.sort(key = myfunc)  
print(thislist)
```

[Try it Yourself »](#)

Case Insensitive Sort

By default the `sort()` method is case sensitive, resulting in all capital letters being sorted before lower case letters:

Example

Case sensitive sorting can give an unexpected result:

```
thislist = ["banana", "Orange", "Kiwi", "cherry"]  
thislist.sort()  
print(thislist)
```

[Try it Yourself »](#)

Reverse Order

What if you want to reverse the order of a list, regardless of the alphabet?

The `reverse()` method reverses the current sorting order of the elements.

Example

Reverse the order of the list items:

```
thislist = ["banana", "Orange", "Kiwi", "cherry"]  
thislist.reverse()  
print(thislist)
```

[Try it Yourself »](#)

Copy a List

You cannot copy a list simply by typing `list2 = list1`, because: `list2` will only be a *reference* to `list1`, and changes made in `list1` will automatically also be made in `list2`.

There are ways to make a copy, one way is to use the built-in List method `copy()`.

Example

Make a copy of a list with the `copy()` method:

```
thislist = ["apple", "banana", "cherry"]  
mylist = thislist.copy()  
print(mylist)
```

[Try it Yourself »](#)

Another way to make a copy is to use the built-in method `list()`.

Example

Make a copy of a list with the `list()` method:

```
thislist = ["apple", "banana", "cherry"]  
mylist = list(thislist)  
print(mylist)
```

[Try it Yourself »](#)

Join Two Lists

There are several ways to join, or concatenate, two or more lists in Python.

One of the easiest ways are by using the `+` operator.

Example

Join two list:

```
list1 = ["a", "b", "c"]  
list2 = [1, 2, 3]  
  
list3 = list1 + list2  
print(list3)
```

[Try it Yourself »](#)

Another way to join two lists is by appending all the items from list2 into list1, one by one:

Example

Append list2 into list1:

```
list1 = ["a", "b" , "c"]  
list2 = [1, 2, 3]  
  
for x in list2:  
    list1.append(x)  
  
print(list1)
```

[Try it Yourself »](#)

Or you can use the `extend()` method, which purpose is to add elements from one list to another list:

Example

Use the `extend()` method to add list2 at the end of list1:

```
list1 = ["a", "b" , "c"]  
list2 = [1, 2, 3]  
  
list1.extend(list2)  
print(list1)
```

[Try it Yourself »](#)

Access Tuple Items

You can access tuple items by referring to the index number, inside square brackets:

Example

Print the second item in the tuple:

```
thistuple = ("apple", "banana", "cherry")  
print(thistuple[1])
```

[Try it Yourself »](#)

Negative Indexing

Negative indexing means start from the end.

`-1` refers to the last item, `-2` refers to the second last item etc.

Example

Print the last item of the tuple:

```
thistuple = ("apple", "banana", "cherry")  
print(thistuple[-1])
```

[Try it Yourself »](#)

Range of Indexes

You can specify a range of indexes by specifying where to start and where to end the range.

When specifying a range, the return value will be a new tuple with the specified items.

Example

Return the third, fourth, and fifth item:

```
thistuple = ("apple", "banana", "cherry", "orange", "kiwi", "melon", "mango")  
print(thistuple[2:5])
```

[Try it Yourself »](#)

TUPLES

By leaving out the start value, the range will start at the first item:

Example

This example returns the items from the beginning to, but NOT included, "kiwi":

```
thistuple = ("apple", "banana", "cherry", "orange", "kiwi", "melon", "mango")  
print(thistuple[:4])
```

[Try it Yourself »](#)

By leaving out the end value, the range will go on to the end of the list:

Example

This example returns the items from "cherry" and to the end:

```
thistuple = ("apple", "banana", "cherry", "orange", "kiwi", "melon", "mango")  
print(thistuple[2:])
```

[Try it Yourself »](#)

Range of Negative Indexes

Specify negative indexes if you want to start the search from the end of the tuple:

Example

This example returns the items from index -4 (included) to index -1 (excluded)

```
thistuple = ("apple", "banana", "cherry", "orange", "kiwi", "melon", "mango")  
print(thistuple[-4:-1])
```

[Try it Yourself »](#)

Check if Item Exists

To determine if a specified item is present in a tuple use the `in` keyword:

Example

Check if "apple" is present in the tuple:

```
thistuple = ("apple", "banana", "cherry")
if "apple" in thistuple:
    print("Yes, 'apple' is in the fruits tuple")
```

[Try it Yourself »](#)

Change Tuple Values

Once a tuple is created, you cannot change its values. Tuples are **unchangeable**, or **immutable** as it also is called.

But there is a workaround. You can convert the tuple into a list, change the list, and convert the list back into a tuple.

Example

Convert the tuple into a list to be able to change it:

```
x = ("apple", "banana", "cherry")
y = list(x)
y[1] = "kiwi"
x = tuple(y)

print(x)
```

[Try it Yourself »](#)

Add Items

Since tuples are immutable, they do not have a build-in `append()` method, but there are other ways to add items to a tuple.

1. **Convert into a list:** Just like the workaround for *changing* a tuple, you can convert it into a list, add your item(s), and convert it back into a tuple.

Example

Convert the tuple into a list, add "orange", and convert it back into a tuple:

```
thistuple = ("apple", "banana", "cherry")  
y = list(thistuple)  
y.append("orange")  
thistuple = tuple(y)
```

[Try it Yourself »](#)

TUPLES

2. **Add tuple to a tuple.** You are allowed to add tuples to tuples, so if you want to add one item, (or many), create a new tuple with the item(s), and add it to the existing tuple:

Example

Create a new tuple with the value "orange", and add that tuple:

```
thistuple = ("apple", "banana", "cherry")
y = ("orange",)
thistuple += y

print(thistuple)
```

[Try it Yourself »](#)

Remove Items

Note: You cannot remove items in a tuple.

Tuples are **unchangeable**, so you cannot remove items from it, but you can use the same workaround as we used for changing and adding tuple items:

Example

Convert the tuple into a list, remove "apple", and convert it back into a tuple:

```
thistuple = ("apple", "banana", "cherry")  
y = list(thistuple)  
y.remove("apple")  
thistuple = tuple(y)
```

[Try it Yourself »](#)

Or you can delete the tuple completely:

Example

The `del` keyword can delete the tuple completely:

```
thistuple = ("apple", "banana", "cherry")
del thistuple
print(thistuple) #this will raise an error because the tuple no longer exists
```

[Try it Yourself »](#)

Unpacking a Tuple

When we create a tuple, we normally assign values to it. This is called "packing" a tuple:

Example

Packing a tuple:

```
fruits = ("apple", "banana", "cherry")
```

[Try it Yourself »](#)

But, in Python, we are also allowed to extract the values back into variables. This is called "unpacking":

Example

Unpacking a tuple:

```
fruits = ("apple", "banana", "cherry")
```

```
(green, yellow, red) = fruits
```

```
print(green)
```

```
print(yellow)
```

```
print(red)
```

[Try it Yourself »](#)

Using Asterisk *

If the number of variables is less than the number of values, you can add an * to the variable name and the values will be assigned to the variable as a list:

Example

Assign the rest of the values as a list called "red":

```
fruits = ("apple", "banana", "cherry", "strawberry", "raspberry")

(green, yellow, *red) = fruits

print(green)
print(yellow)
print(red)
```

[Try it Yourself »](#)

TUPLES

If the asterisk is added to another variable name than the last, Python will assign values to the variable until the number of values left matches the number of variables left.

Example

Add a list of values the "tropic" variable:

```
fruits = ("apple", "mango", "papaya", "pineapple", "cherry")

(green, *tropic, red) = fruits

print(green)
print(tropic)
print(red)
```

[Try it Yourself »](#)

Loop Through a Tuple

You can loop through the tuple items by using a `for` loop.

Example

Iterate through the items and print the values:

```
thistuple = ("apple", "banana", "cherry")  
for x in thistuple:  
    print(x)
```

[Try it Yourself »](#)

Loop Through the Index Numbers

You can also loop through the tuple items by referring to their index number.

Use the `range()` and `len()` functions to create a suitable iterable.

Example

Print all items by referring to their index number:

```
thistuple = ("apple", "banana", "cherry")
for i in range(len(thistuple)):
    print(thistuple[i])
```

[Try it Yourself »](#)

Using a While Loop

You can loop through the list items by using a `while` loop.

Use the `len()` function to determine the length of the tuple, then start at 0 and loop your way through the tuple items by referring to their indexes.

Remember to increase the index by 1 after each iteration.

Example

Print all items, using a `while` loop to go through all the index numbers:

```
thistuple = ("apple", "banana", "cherry")
i = 0
while i < len(thistuple):
    print(thistuple[i])
    i = i + 1
```

[Try it Yourself »](#)

Join Two Tuples

To join two or more tuples you can use the `+` operator:

Example

Join two tuples:

```
tuple1 = ("a", "b" , "c")  
tuple2 = (1, 2, 3)  
  
tuple3 = tuple1 + tuple2  
print(tuple3)
```

[Try it Yourself »](#)

Multiply Tuples

If you want to multiply the content of a tuple a given number of times, you can use the `*` operator:

Example

Multiply the fruits tuple by 2:

```
fruits = ("apple", "banana", "cherry")  
mytuple = fruits * 2  
  
print(mytuple)
```

[Try it Yourself »](#)

Tuple Methods

Python has two built-in methods that you can use on tuples.

Method	Description
<u>count()</u>	Returns the number of times a specified value occurs in a tuple
<u>index()</u>	Searches the tuple for a specified value and returns the position of where it was found

Access Items

You cannot access items in a set by referring to an index or a key.

But you can loop through the set items using a `for` loop, or ask if a specified value is present in a set, by using the `in` keyword.

Example

Loop through the set, and print the values:

```
thisset = {"apple", "banana", "cherry"}  
  
for x in thisset:  
    print(x)
```

[Try it Yourself »](#)

Example

Check if "banana" is present in the set:

```
thisset = {"apple", "banana", "cherry"}  
  
print("banana" in thisset)
```

[Try it Yourself »](#)

Add Items

Once a set is created, you cannot change its items, but you can add new items.

To add one item to a set use the `add()` method.

Example

Add an item to a set, using the `add()` method:

```
thisset = {"apple", "banana", "cherry"}  
  
thisset.add("orange")  
  
print(thisset)
```

[Try it Yourself »](#)

Add Sets

To add items from another set into the current set, use the `update()` method.

Example

Add elements from `tropical` into `thisset`:

```
thisset = {"apple", "banana", "cherry"}  
tropical = {"pineapple", "mango", "papaya"}  
  
thisset.update(tropical)  
  
print(thisset)
```

[Try it Yourself »](#)

Add Any Iterable

The object in the `update()` method does not have to be a set, it can be any iterable object (tuples, lists, dictionaries etc.).

Example

Add elements of a list to a set:

```
thisset = {"apple", "banana", "cherry"}  
mylist = ["kiwi", "orange"]  
  
thisset.update(mylist)  
  
print(thisset)
```

[Try it Yourself »](#)

Remove Item

To remove an item in a set, use the `remove()`, or the `discard()` method.

Example

Remove "banana" by using the `remove()` method:

```
thisset = {"apple", "banana", "cherry"}  
  
thisset.remove("banana")  
  
print(thisset)
```

[Try it Yourself »](#)

Note: If the item to remove does not exist, `remove()` will raise an error.

Example

Remove "banana" by using the `discard()` method:

```
thisset = {"apple", "banana", "cherry"}  
  
thisset.discard("banana")  
  
print(thisset)
```

[Try it Yourself »](#)

Note: If the item to remove does not exist, `discard()` will **NOT** raise an error.

You can also use the `pop()` method to remove an item, but this method will remove the *last* item. Remember that sets are unordered, so you will not know what item that gets removed.

The return value of the `pop()` method is the removed item.

Example

Remove the last item by using the `pop()` method:

```
thisset = {"apple", "banana", "cherry"}  
  
x = thisset.pop()  
  
print(x)  
  
print(thisset)
```

[Try it Yourself »](#)

Example

The `clear()` method empties the set:

```
thisset = {"apple", "banana", "cherry"}  
  
thisset.clear()  
  
print(thisset)
```

[Try it Yourself »](#)

Example

The `del` keyword will delete the set completely:

```
thisset = {"apple", "banana", "cherry"}  
  
del thisset  
  
print(thisset)
```

[Try it Yourself »](#)

Join Two Sets

There are several ways to join two or more sets in Python.

You can use the `union()` method that returns a new set containing all items from both sets, or the `update()` method that inserts all the items from one set into another:

Example

The `union()` method returns a new set with all items from both sets:

```
set1 = {"a", "b" , "c"}  
set2 = {1, 2, 3}  
  
set3 = set1.union(set2)  
print(set3)
```

[Try it Yourself »](#)

Example

The `update()` method inserts the items in set2 into set1:

```
set1 = {"a", "b" , "c"}  
set2 = {1, 2, 3}  
  
set1.update(set2)  
print(set1)
```

[Try it Yourself »](#)

Note: Both `union()` and `update()` will exclude any duplicate items.

Keep ONLY the Duplicates

The `intersection_update()` method will keep only the items that are present in both sets.

Example

Keep the items that exist in both set `x`, and set `y` :

```
x = {"apple", "banana", "cherry"}  
y = {"google", "microsoft", "apple"}  
  
x.intersection_update(y)  
  
print(x)
```

[Try it Yourself »](#)

The `intersection()` method will return a *new* set, that only contains the items that are present in both sets.

Example

Return a set that contains the items that exist in both set `x`, and set `y` :

```
x = {"apple", "banana", "cherry"}  
y = {"google", "microsoft", "apple"}  
  
z = x.intersection(y)  
  
print(z)
```

[Try it Yourself »](#)

Keep All, But NOT the Duplicates

The `symmetric_difference_update()` method will keep only the elements that are NOT present in both sets.

Example

Keep the items that are not present in both sets:

```
x = {"apple", "banana", "cherry"}  
y = {"google", "microsoft", "apple"}  
  
x.symmetric_difference_update(y)  
  
print(x)
```

[Try it Yourself »](#)

The `symmetric_difference()` method will return a new set, that contains only the elements that are NOT present in both sets.

Example

Return a set that contains all items from both sets, except items that are present in both:

```
x = {"apple", "banana", "cherry"}  
y = {"google", "microsoft", "apple"}  
  
z = x.symmetric_difference(y)  
  
print(z)
```

[Try it Yourself »](#)

Set Methods

Python has a set of built-in methods that you can use on sets.

Method	Description
<u>add()</u>	Adds an element to the set
<u>clear()</u>	Removes all the elements from the set
<u>copy()</u>	Returns a copy of the set
<u>difference()</u>	Returns a set containing the difference between two or more sets
<u>difference_update()</u>	Removes the items in this set that are also included in another, specified set
<u>discard()</u>	Remove the specified item
<u>intersection()</u>	Returns a set, that is the intersection of two other sets
<u>intersection_update()</u>	Removes the items in this set that are not present in other, specified set(s)
<u>isdisjoint()</u>	Returns whether two sets have a intersection or not

Set Methods

Python has a set of built-in methods that you can use on sets.

Method	Description
<code>issubset()</code>	Returns whether another set contains this set or not
<code>issuperset()</code>	Returns whether this set contains another set or not
<code>pop()</code>	Removes an element from the set
<code>remove()</code>	Removes the specified element
<code>symmetric_difference()</code>	Returns a set with the symmetric differences of two sets
<code>symmetric_difference_update()</code>	inserts the symmetric differences from this set and another
<code>union()</code>	Return a set containing the union of sets
<code>update()</code>	Update the set with the union of this set and others

```
thisdict = {  
    "brand": "Ford",  
    "model": "Mustang",  
    "year": 1964  
}
```

Dictionary

Dictionaries are used to store data values in key:value pairs.

A dictionary is a collection which is ordered*, changeable and does not allow duplicates.

As of Python version 3.7, dictionaries are *ordered*. In Python 3.6 and earlier, dictionaries are *unordered*.

Example

Create and print a dictionary:

```
thisdict = {  
    "brand": "Ford",  
    "model": "Mustang",  
    "year": 1964  
}  
print(thisdict)
```

[Try it Yourself »](#)

Dictionary Items

Dictionary items are ordered, changeable, and does not allow duplicates.

Dictionary items are presented in key:value pairs, and can be referred to by using the key name.

Example

Print the "brand" value of the dictionary:

```
thisdict = {  
    "brand": "Ford",  
    "model": "Mustang",  
    "year": 1964  
}  
print(thisdict["brand"])
```

[Try it Yourself »](#)

Duplicates Not Allowed

Dictionaries cannot have two items with the same key:

Example

Duplicate values will overwrite existing values:

```
thisdict = {  
    "brand": "Ford",  
    "model": "Mustang",  
    "year": 1964,  
    "year": 2020  
}  
print(thisdict)
```

[Try it Yourself »](#)

Dictionary Length

To determine how many items a dictionary has, use the `len()` function:

Example

Print the number of items in the dictionary:

```
print(len(thisdict))
```

[Try it Yourself »](#)

Dictionary Items - Data Types

The values in dictionary items can be of any data type:

Example

String, int, boolean, and list data types:

```
thisdict = {  
    "brand": "Ford",  
    "electric": False,  
    "year": 1964,  
    "colors": ["red", "white", "blue"]  
}
```

[Try it Yourself »](#)

type()

From Python's perspective, dictionaries are defined as objects with the data type 'dict':

```
<class 'dict'>
```

Example

Print the data type of a dictionary:

```
thisdict = {  
    "brand": "Ford",  
    "model": "Mustang",  
    "year": 1964  
}  
print(type(thisdict))
```

[Try it Yourself »](#)

Accessing Items

You can access the items of a dictionary by referring to its key name, inside square brackets:

Example

Get the value of the "model" key:

```
thisdict = {  
    "brand": "Ford",  
    "model": "Mustang",  
    "year": 1964  
}  
x = thisdict["model"]
```

[Try it Yourself »](#)

There is also a method called `get()` that will give you the same result:

Example

Get the value of the "model" key:

```
x = thisdict.get("model")
```

[Try it Yourself »](#)

Get Keys

The `keys()` method will return a list of all the keys in the dictionary.

Example

Get a list of the keys:

```
x = thisdict.keys()
```

[Try it Yourself »](#)

The list of the keys is a *view* of the dictionary, meaning that any changes done to the dictionary will be reflected in the keys list.

Example

Add a new item to the original dictionary, and see that the keys list gets updated as well:

```
car = {  
    "brand": "Ford",  
    "model": "Mustang",  
    "year": 1964  
}  
  
x = car.keys()  
  
print(x) #before the change  
  
car["color"] = "white"  
  
print(x) #after the change
```

[Try it Yourself »](#)

Get Values

The `values()` method will return a list of all the values in the dictionary.

Example

Get a list of the values:

```
x = thisdict.values()
```

[Try it Yourself »](#)

The list of the values is a *view* of the dictionary, meaning that any changes done to the dictionary will be reflected in the values list.

Example

Make a change in the original dictionary, and see that the values list gets updated as well:

```
car = {  
    "brand": "Ford",  
    "model": "Mustang",  
    "year": 1964  
}  
  
x = car.values()  
  
print(x) #before the change  
  
car["year"] = 2020  
  
print(x) #after the change
```

Example

Add a new item to the original dictionary, and see that the values list gets updated as well:

```
car = {  
    "brand": "Ford",  
    "model": "Mustang",  
    "year": 1964  
}  
  
x = car.values()  
  
print(x) #before the change  
  
car["color"] = "red"  
  
print(x) #after the change
```

[Try it Yourself »](#)

Get Items

The `items()` method will return each item in a dictionary, as tuples in a list.

Example

Get a list of the key:value pairs

```
x = thisdict.items()
```

[Try it Yourself »](#)

The returned list is a *view* of the items of the dictionary, meaning that any changes done to the dictionary will be reflected in the items list.

Example

Make a change in the original dictionary, and see that the items list gets updated as well:

```
car = {  
    "brand": "Ford",  
    "model": "Mustang",  
    "year": 1964  
}  
  
x = car.items()  
  
print(x) #before the change  
  
car["year"] = 2020  
  
print(x) #after the change
```

[Try it Yourself »](#)

Example

Add a new item to the original dictionary, and see that the items list gets updated as well:

```
car = {  
    "brand": "Ford",  
    "model": "Mustang",  
    "year": 1964  
}  
  
x = car.items()  
  
print(x) #before the change  
  
car["color"] = "red"  
  
print(x) #after the change
```

[Try it Yourself »](#)

Check if Key Exists

To determine if a specified key is present in a dictionary use the `in` keyword:

Example

Check if "model" is present in the dictionary:

```
thisdict = {  
    "brand": "Ford",  
    "model": "Mustang",  
    "year": 1964  
}  
if "model" in thisdict:  
    print("Yes, 'model' is one of the keys in the thisdict dictionary")
```

[Try it Yourself »](#)

Change Values

You can change the value of a specific item by referring to its key name:

Example

Change the "year" to 2018:

```
thisdict = {  
    "brand": "Ford",  
    "model": "Mustang",  
    "year": 1964  
}  
thisdict["year"] = 2018
```

[Try it Yourself »](#)

Update Dictionary

The `update()` method will update the dictionary with the items from the given argument.

The argument must be a dictionary, or an iterable object with key:value pairs.

Example

Update the "year" of the car by using the `update()` method:

```
thisdict = {  
    "brand": "Ford",  
    "model": "Mustang",  
    "year": 1964  
}  
thisdict.update({"year": 2020})
```

[Try it Yourself »](#)

Adding Items

Adding an item to the dictionary is done by using a new index key and assigning a value to it:

Example

```
thisdict = {  
    "brand": "Ford",  
    "model": "Mustang",  
    "year": 1964  
}  
thisdict["color"] = "red"  
print(thisdict)
```

[Try it Yourself »](#)

Update Dictionary

The `update()` method will update the dictionary with the items from a given argument. If the item does not exist, the item will be added.

The argument must be a dictionary, or an iterable object with key:value pairs.

Example

Add a color item to the dictionary by using the `update()` method:

```
thisdict = {  
    "brand": "Ford",  
    "model": "Mustang",  
    "year": 1964  
}  
thisdict.update({"color": "red"})
```

[Try it Yourself »](#)

Removing Items

There are several methods to remove items from a dictionary:

Example

The `pop()` method removes the item with the specified key name:

```
thisdict = {  
    "brand": "Ford",  
    "model": "Mustang",  
    "year": 1964  
}  
thisdict.pop("model")  
print(thisdict)
```

[Try it Yourself »](#)

Example

The `popitem()` method removes the last inserted item (in versions before 3.7, a random item is removed instead):

```
thisdict = {  
    "brand": "Ford",  
    "model": "Mustang",  
    "year": 1964  
}  
thisdict.popitem()  
print(thisdict)
```

[Try it Yourself »](#)

Example

The `del` keyword removes the item with the specified key name:

```
thisdict = {  
    "brand": "Ford",  
    "model": "Mustang",  
    "year": 1964  
}  
del thisdict["model"]  
print(thisdict)
```

[Try it Yourself »](#)

Example

The `del` keyword can also delete the dictionary completely:

```
thisdict = {  
    "brand": "Ford",  
    "model": "Mustang",  
    "year": 1964  
}  
del thisdict  
print(thisdict) #this will cause an error because "thisdict" no longer exists.
```

[Try it Yourself »](#)

Example

The `clear()` method empties the dictionary:

```
thisdict = {  
    "brand": "Ford",  
    "model": "Mustang",  
    "year": 1964  
}  
thisdict.clear()  
print(thisdict)
```

[Try it Yourself »](#)

Loop Through a Dictionary

You can loop through a dictionary by using a `for` loop.

When looping through a dictionary, the return value are the *keys* of the dictionary, but there are methods to return the *values* as well.

Example

Print all key names in the dictionary, one by one:

```
for x in thisdict:  
    print(x)
```

[Try it Yourself »](#)

Example

Print all *values* in the dictionary, one by one:

```
for x in thisdict:  
    print(thisdict[x])
```

[Try it Yourself »](#)

Example

You can also use the `values()` method to return values of a dictionary:

```
for x in thisdict.values():  
    print(x)
```

[Try it Yourself »](#)

Example

You can use the `keys()` method to return the keys of a dictionary:

```
for x in thisdict.keys():  
    print(x)
```

[Try it Yourself »](#)

Example

Loop through both *keys* and *values*, by using the `items()` method:

```
for x, y in thisdict.items():  
    print(x, y)
```

[Try it Yourself »](#)

Another way to make a copy is to use the built-in function `dict()`.

Example

Make a copy of a dictionary with the `dict()` function:

```
thisdict = {  
    "brand": "Ford",  
    "model": "Mustang",  
    "year": 1964  
}  
mydict = dict(thisdict)  
print(mydict)
```

[Try it Yourself »](#)

Nested Dictionaries

A dictionary can contain dictionaries, this is called nested dictionaries.

Example

Create a dictionary that contain three dictionaries:

```
myfamily = {  
    "child1" : {  
        "name" : "Emil",  
        "year" : 2004  
    },  
    "child2" : {  
        "name" : "Tobias",  
        "year" : 2007  
    },  
    "child3" : {  
        "name" : "Linus",  
        "year" : 2011  
    }  
}
```

Dictionary Methods

Python has a set of built-in methods that you can use on dictionaries.

Method	Description
<code>clear()</code>	Removes all the elements from the dictionary
<code>copy()</code>	Returns a copy of the dictionary
<code>fromkeys()</code>	Returns a dictionary with the specified keys and value
<code>get()</code>	Returns the value of the specified key
<code>items()</code>	Returns a list containing a tuple for each key value pair
<code>keys()</code>	Returns a list containing the dictionary's keys
<code>pop()</code>	Removes the element with the specified key
<code>popitem()</code>	Removes the last inserted key-value pair
<code>setdefault()</code>	Returns the value of the specified key. If the key does not exist: insert the key, with the specified value
<code>update()</code>	Updates the dictionary with the specified key-value pairs

EXERCISE TIME

19. Write a Python program to convert a list of tuples into a dictionary. [Go to the editor](#)

[Click me to see the sample solution](#)

```
# initializing the list
tuples = [('Key 1', 1), ('Key 2', 2), ('Key 3', 3), ('Key 4', 4), ('Key 5', 5)]

# converting to dict
result = dict(tuples)

# printing the result
print(result)
```

If you run the above code, you will get the following result.

Output

```
{'Key 1': 1, 'Key 2': 2, 'Key 3': 3, 'Key 4': 4, 'Key 5': 5}
```
